SO(14) Unification: A Machine-Verified Algebraic Scaffold with Phenomenological Predictions

Ian M. Arnoldy[1]

[1] *Independent Researcher*

(Dated: March 9, 2026)

We present a candidate unified field theory based on SO(14), whose algebraic foundation has been machine-verified in Lean 4 with the mathlib library: 37 proof files containing approximately 980 theorems with zero `sorry` gaps. The SO(14) Lie algebra has 91 generators, which decompose as $91 = 45 + 6 + 40$ under $\mathfrak{so}(10) \oplus \mathfrak{so}(4) \oplus$ mixed, embedding both the Standard Model gauge group and a gravity sector in a single algebraic structure. We construct the symmetry-breaking chain $\mathrm{SO}(14) \to \mathrm{SO}(10) \times \mathrm{SO}(4) \to \mathrm{SU}(5) \times \mathrm{U}(1) \to \mathrm{SU}(3) \times \mathrm{SU}(2) \times \mathrm{U}(1) \to \mathrm{U}(1)_{\mathrm{EM}}$, identifying the symmetric traceless 104-dimensional representation as the Higgs field for the first step. One-loop renormalization group analysis yields coupling unification at $M_{\mathrm{GUT}} = 10^{16.98}\,\mathrm{GeV}$ with $\alpha_{\mathrm{GUT}}^{-1} = 47.03$ (0.88% miss with threshold corrections from 178 scalar components), a proton lifetime of $\tau_p \approx 10^{38.9}$ years (safely above the Super-Kamiokande bound of $10^{34.4}$ years), and asymptotic freedom at all scales above the Standard Model. We state open problems honestly: the three-generation problem is inherited from SO(10), the Distler ghost objection for the non-compact form $\mathrm{SO}(3,11)$ remains unresolved, and the mass gap is the Millennium Prize problem. Machine verification is the unique methodological contribution: 83% of our theorems are signature-independent, holding for all real forms of $\mathfrak{so}(14,\mathbb{C})$. To our knowledge, this is the first grand unified theory whose algebraic foundation has been formally verified by an interactive theorem prover.

I. INTRODUCTION

The search for a unified description of the fundamental forces has been a central program in theoretical physics since Einstein's attempts at a unified field theory [1]. The Standard Model of particle physics, based on the gauge group $\mathrm{SU}(3) \times \mathrm{SU}(2) \times \mathrm{U}(1)$, provides a spectacularly successful description of the strong, weak, and electromagnetic interactions [4–6], but leaves gravity outside its framework and contains 19 free parameters that are not explained.

Grand unified theories (GUTs) embed the Standard Model gauge group in a simple Lie group, achieving partial unification of the non-gravitational forces [7–9]. The progression $\mathrm{SU}(5) \subset \mathrm{SO}(10) \subset \mathrm{E}_6$ offers increasingly complete unification, with SO(10) providing the most economical scheme: all 15 Standard Model fermions of one generation, plus a right-handed neutrino, fit in a single 16-dimensional spinor representation [8].

Gravity-gauge unification has been pursued through several approaches: Kaluza-Klein theory [2, 3], supergravity [29], and string theory [30]. A less explored but algebraically natural path embeds the Lorentz group $\mathrm{SO}(1,3)$ together with the gauge group inside a single orthogonal group [13–15]. The minimal group that accommodates both SO(10) (gauge) and $\mathrm{SO}(1,3)$ (gravity) is SO(14), or more precisely its non-compact real form $\mathrm{SO}(3,11)$ [14, 15].

In this paper we present a candidate SO(14) unified theory with a distinctive feature: the algebraic foundation has been machine-verified using the Lean 4 interactive theorem prover [35] and the mathlib library [36]. Specifically, 37 Lean 4 proof files containing approximately 980 theorems have been compiled with zero `sorry` gaps (unproved assertions). This means that the algebraic structure—dimensions, embeddings, anomaly cancellation, representation decompositions, breaking chain, beta-function coefficients, and more—has been checked by computer with the same level of rigor as the proofs in the Flyspeck project [37] or the liquid tensor experiment [38].

To our knowledge, this is the first grand unified theory to receive machine verification of its algebraic structure. We emphasize from the outset the distinction between what is proved and what is proposed:

- **Machine-verified** [MV]: Algebraic identities, dimensions, embeddings, anomaly cancellation, Standard Model beta-function coefficients, and Goldstone boson counting. These are properties of the complex Lie algebra $\mathfrak{so}(14,\mathbb{C})$ and its representations, holding for all real forms including $\mathrm{SO}(3,11)$.
- **Computed** [CO]: Renormalization group running, coupling unification, proton lifetime, breaking chain physics.
- **Candidate physics** [CP]: The proposal that SO(14) (or $\mathrm{SO}(3,11)$) describes nature, the specific Higgs sector, the three-generation mechanism.
- **Open problems** [OP]: Three generations, Distler ghost objection, mass gap.

Machine verification does not prove that SO(14) describes nature. It proves that the algebraic scaffold is internally consistent: the dimensions add up, the embeddings are valid Lie algebra homomorphisms, the anomalies cancel, and the breaking chain produces the correct

Standard Model gauge group with the correct particle content. Whether this scaffold corresponds to physical reality is a separate question that only experiment can answer.

The paper is organized as follows. Section II summarizes the machine-verified foundation. Section III constructs the SO(14) model: algebraic structure, breaking chain, matter content, and signature. Section IV presents the renormalization group analysis. Section V derives phenomenological predictions. Section VI discusses open problems and compares with other unification proposals. Section VII concludes.

II. MACHINE-VERIFIED FOUNDATION

A. Lean 4 Proof Methodology

All algebraic results are formalized in Lean 4 [35], a dependently-typed programming language and interactive theorem prover. Lean 4's type theory ensures that every theorem is deductively valid: the compiler rejects any proof containing logical gaps. The mathlib library [36] provides the mathematical infrastructure (real and complex numbers, linear algebra, ring theory).

Our proof strategy uses explicit finite-dimensional representations rather than mathlib's abstract `CliffordAlgebra` type. This choice prioritizes computational transparency: proofs reduce to `ext` (extensionality), `simp` (simplification), `ring` (polynomial identity), and `native_decide` (decidable computation), making them independently auditable. The complete methodology is described in the companion paper [41].

The codebase compiles as a single Lean 4 project (3,298 build jobs, zero errors, zero `sorry` gaps) and is publicly available [43].

B. Key Machine-Verified Results

Table I summarizes the principal machine-verified theorems relevant to the SO(14) model.

C. Clifford Algebra Hierarchy

The algebraic path to SO(14) proceeds through a hierarchy of Clifford algebras [42]:

$$\mathrm{Cl}(1,1) \hookrightarrow \mathrm{Cl}(1,3) \hookrightarrow \mathrm{Cl}(6) \hookrightarrow \mathrm{Cl}(10) \hookrightarrow \mathrm{Cl}(14). \quad (1)$$

At each level, the grade-2 elements form a Lie algebra under the commutator bracket (the "grade-2 Lie algebra functor"[MV]):

$$\mathrm{Cl}^2(n,0) \cong \mathfrak{so}(n), \qquad [A,B] = AB - BA. \quad (2)$$

This construction produces the chain

$$\mathfrak{so}(1,1) \hookrightarrow \mathfrak{so}(1,3) \hookrightarrow \mathfrak{so}(6) \hookrightarrow \mathfrak{so}(10) \hookrightarrow \mathfrak{so}(14), \quad (3)$$

where $\mathfrak{so}(6) \cong \mathfrak{su}(4)$ (Pati-Salam), $\mathfrak{so}(10)$ (Georgi-Glashow-Fritzsch), and $\mathfrak{so}(14)$ (this work).

D. What Machine Verification Does and Does Not Prove

Machine verification proves that the algebraic identities are *deductively valid*: if the axioms of Lean 4's type theory and the definitions in mathlib are consistent, then the theorems hold. This is a stronger guarantee than peer review, which checks plausibility rather than logical validity.

Machine verification does *not* prove:

1. That SO(14) describes nature (an empirical question).
2. That the full quantum field theory is well-defined (the mass gap problem[OP]).
3. That the non-compact form SO(3, 11) is ghost-free (the Distler objection[OP]).
4. That three generations arise naturally (open for all GUTs[OP]).

A signature audit of all 37 proof files [43] classifies 83% as *signature-independent* (properties of $\mathfrak{so}(14,\mathbb{C})$, holding for all real forms), 8% as *compact-only* (energy positivity results that fail for SO(3, 11) above the breaking scale), and 8% as *needs-revision* (results stated for a specific signature with natural Lorentzian analogues).

III. THE SO(14) MODEL

A. Algebraic Structure

The Lie algebra $\mathfrak{so}(14)$ has dimension $\binom{14}{2} = 91$[MV]. Under the subalgebra decomposition $\mathfrak{so}(14) \supset \mathfrak{so}(10) \oplus \mathfrak{so}(4)$, the 91 generators decompose as[MV]

$$91 = \underbrace{45}_{\text{gauge}} + \underbrace{6}_{\text{gravity}} + \underbrace{40}_{\text{mixed}}, \quad (4)$$

where:

- The 45 generators of $\mathfrak{so}(10) \cong \mathfrak{su}(5) \oplus \cdots$ contain the Standard Model gauge bosons plus leptoquarks.
- The 6 generators of $\mathfrak{so}(4) \cong \mathfrak{su}(2) \times \mathfrak{su}(2)$ are identified with the Lorentz group in the non-compact form $\mathfrak{so}(3,1)$.[CP]
- The 40 generators in the $(\mathbf{10}, \mathbf{4})$ bifundamental representation mix gauge and gravitational indices.[MV]

TABLE I. Principal machine-verified results. All proofs compile with zero `sorry` gaps in Lean 4 with mathlib.

Result	**Lean File**	**Key Theorem**	**Content**
$\dim \mathfrak{so}(14) = \binom{14}{2} = 91$	`so14_unification`	`so14_dimension`	Dimension counting
$91 = 45 + 6 + 40$	`so14_unification`	`unification_decomposition`	Gauge + gravity + mixed
$\mathrm{SU}(5) \subset \mathrm{SO}(10)$ via $[\mathfrak{g}, J] = 0$	`su5_so10_embedding`	`centralizer_closed`	Complex structure embedding
All 6 anomaly conditions	`so14_anomalies`	`anomaly_checklist`	SO(14) anomaly freedom
$Q = T_3 + Y/2$ preserves VEV	`symmetry_breaking`	`charge_preserves_vev`	Photon masslessness
$16 = 1 + 10 + \overline{5}$	`spinor_matter`	`spinor_weight_decomposition`	One generation per spinor
Higgs: sym. traceless **104**	`so14_breaking_chain`	`so14_sym_traceless_dim`	Corrected Higgs rep
75 massive +16 massless = 91	`so14_breaking_chain`	`gauge_boson_conservation`	Mass spectrum accounting
$[\mathfrak{so}(1,3), \mathfrak{so}(10)] = 0$	`unification_gravity`	`commutator_vanishes`	Gravity-gauge decoupling
SM beta coefficients	`rg_running`	`beta1_gut_normalized`	b_1, b_2, b_3 from reps
Jacobi identity for $\mathfrak{so}(10)$	`so10_grand`	`jacobi_cyclic`	Lie algebra axiom
$\nabla \cdot B = 0$ from Bianchi	`bianchi_identity`	`gauss_law_magnetism`	Maxwell from algebra

The crucial algebraic fact is that the gauge and gravity subalgebras commute[MV]:

$$[\mathfrak{so}(10), \mathfrak{so}(4)] = 0 \quad \text{in } \mathfrak{so}(14), \tag{5}$$

which holds because the two subalgebras act on disjoint index sets (indices 1–10 vs. 11–14). The Kronecker deltas on disjoint indices vanish, forcing the bracket to zero. This result is signature-independent: it holds for $\mathfrak{so}(14, \mathbb{C})$ and all its real forms.[MV]

The SO(14) algebra is anomaly-free. All six standard anomaly conditions—including the quartic d-symbol trace $\binom{93}{3} = 129{,}766$—are machine-verified.[MV] Anomaly cancellation is a property of the complex Lie algebra and holds for all real forms, including $\mathrm{SO}(3, 11)$.

B. Breaking Chain

The symmetry-breaking chain from SO(14) to the Standard Model proceeds in five steps[MV][CO]:

$$\begin{aligned} \mathrm{SO}(14) &\xrightarrow{\mathbf{104}} \mathrm{SO}(10) \times \mathrm{SO}(4) \\ &\xrightarrow{\mathbf{45}} \mathrm{SU}(5) \times \mathrm{U}(1)_\chi \times \mathrm{SO}(4) \\ &\xrightarrow{\mathbf{24}} \mathrm{SU}(3) \times \mathrm{SU}(2) \times \mathrm{U}(1)_Y \times \mathrm{SO}(4) \\ &\xrightarrow{\mathbf{4}} \mathrm{SU}(3) \times \mathrm{U}(1)_{\mathrm{EM}} \times \mathrm{SO}(4). \end{aligned} \tag{6}$$

a. Step 1: $\mathrm{SO}(14) \to \mathrm{SO}(10) \times \mathrm{SO}(4)$. The Higgs field is a symmetric traceless 2-tensor S_{ab} (dimension $14 \times 15/2 - 1 = 104$)[MV], not the adjoint (dimension 91). This distinction is critical: an adjoint VEV breaks $\mathrm{SO}(2n) \to \mathrm{U}(n)$, not to $\mathrm{SO}(2n_1) \times \mathrm{SO}(2n_2)$ [26, 27]. The symmetric traceless VEV $\langle S \rangle = \mathrm{diag}(a, \ldots, a, b, \ldots, b)$ with $10a + 4b = 0$ (tracelessness) preserves exactly $\mathrm{SO}(10) \times \mathrm{SO}(4)$.[MV]

The 104 decomposes under $\mathrm{SO}(10) \times \mathrm{SO}(4)$ as[MV]

$$\mathbf{104} = (\mathbf{54}, \mathbf{1}) \oplus (\mathbf{1}, \mathbf{9}) \oplus (\mathbf{10}, \mathbf{4}) \oplus (\mathbf{1}, \mathbf{1}). \tag{7}$$

The $(\mathbf{10}, \mathbf{4}) = 40$ components are eaten as Goldstone bosons by the 40 broken gauge bosons.[MV] The remaining 64 components become physical massive scalars.

The Higgs potential for the symmetric traceless representation is

$$V(S) = -\mu^2 \mathrm{Tr}(S^2) + \kappa \mathrm{Tr}(S^3) + \lambda_1 [\mathrm{Tr}(S^2)]^2 + \lambda_2 \mathrm{Tr}(S^4), \tag{8}$$

where the cubic invariant $\kappa \neq 0$ is responsible for the $\mathrm{SO}(10) \times \mathrm{SO}(4)$ vacuum alignment (as opposed to $\mathrm{SO}(7) \times \mathrm{SO}(7)$ or other patterns).

b. Steps 2–4. The remaining steps are standard GUT technology [7, 8]: $\mathrm{SO}(10) \to \mathrm{SU}(5) \times \mathrm{U}(1)_\chi$ via an adjoint **45** VEV[MV]; $\mathrm{SU}(5) \to \mathrm{SU}(3) \times \mathrm{SU}(2) \times \mathrm{U}(1)_Y$ via an adjoint **24** VEV[MV]; electroweak breaking via a fundamental Higgs doublet[MV].

c. Mass spectrum. The total number of broken generators across all steps is $40+20+12+3 = 75$[MV], producing 75 massive gauge bosons. The remaining $91 - 75 = 16$ generators are: 8 gluons, 1 photon, 6 SO(4) generators (gravity sector), and 1 $\mathrm{U}(1)_\chi$.[MV] The $\mathrm{U}(1)_\chi$ factor must be broken by an additional scalar (e.g., a spinor **16** of SO(10), contained in the **64** of SO(14)) to avoid a massless gauge boson excluded by experiment[CP]

Table II summarizes the breaking chain with Goldstone boson counting.

C. Matter Content and Generations

The semi-spinor of Spin(14) has dimension $2^{14/2-1} = 2^6 = 64$. Under $\mathrm{SO}(14) \to \mathrm{SO}(10) \times \mathrm{SO}(4)$, where

TABLE II. Symmetry-breaking chain. "Broken" = number of broken generators = Goldstone bosons eaten. "Physical" = remaining scalar components. All dimension counts are machine-verified [MV].

Step	**Higgs**	**dim**	**Broken**	**Physical**
$\mathrm{SO}(14) \to \mathrm{SO}(10) \times \mathrm{SO}(4)$	**104**	104	40	64
$\mathrm{SO}(10) \to \mathrm{SU}(5) \times \mathrm{U}(1)$	**45**	45	20	25
$\mathrm{SU}(5) \to \mathrm{SM}$	**24**	24	12	12
$\mathrm{SU}(2) \times \mathrm{U}(1) \to \mathrm{U}(1)_{\mathrm{EM}}$	**4**	4	3	1
Total		177	75	102

$\mathrm{SO}(4) \cong \mathrm{SU}(2)_a \times \mathrm{SU}(2)_b$, the semi-spinor dimension $2^6 = 64$ is machine-verified[MV]; the branching rule is standard [28][SP]:

$$\mathbf{64}_+ = (\mathbf{16}, (\mathbf{2}, \mathbf{1})) \oplus (\overline{\mathbf{16}}, (\mathbf{1}, \mathbf{2})), \tag{9}$$

$$\mathbf{64}_- = (\overline{\mathbf{16}}, (\mathbf{2}, \mathbf{1})) \oplus (\mathbf{16}, (\mathbf{1}, \mathbf{2})). \tag{10}$$

Each semi-spinor contains exactly one $\mathbf{16}$ of SO(10), which is exactly one generation of Standard Model fermions (including the right-handed neutrino)[CO].[SP] The $\overline{\mathbf{16}}$ is the conjugate representation (antimatter/mirror fermions), and the SU(2) doublet structure reflects the extra SO(4) degrees of freedom.

The full matter content is taken to be three copies of the semi-spinor[CP]:

$$\text{Matter} = 3 \times \mathbf{64}_+ \to 3 \times (\mathbf{16}, (\mathbf{2}, \mathbf{1})) \oplus 3 \times (\overline{\mathbf{16}}, (\mathbf{1}, \mathbf{2})). \tag{11}$$

a. The three-generation problem. The number three is put in by hand, just as in SO(10) with $3 \times \mathbf{16}$[OP]. This is the universal GUT generation problem: no known simple Lie group predicts exactly three generations from representation theory alone. The historical SO(14)-specific literature (Ida, Kayama, and Kitazoe [17]; Ma, Du, Xue, and Zhou [18]) found *four* generations from the full 128-dimensional Dirac spinor, not three. The Wilczek-Zee critique [19] showed that SO(18) family unification fails (8 + 8 mirror families); for SO(14), this critique is much less severe because a single semi-spinor gives only one family.

The $\mathrm{SO}(4) = \mathrm{SU}(2)_L \times \mathrm{SU}(2)_R$ factor that appears in the decomposition $\mathrm{SO}(14) \to \mathrm{SO}(10) \times \mathrm{SO}(4)$ initially suggests a four-sector family structure, since the semi-spinor branches as $\mathbf{64}_+ = (\mathbf{16}, (\mathbf{2}, \mathbf{1})) \oplus (\overline{\mathbf{16}}, (\mathbf{1}, \mathbf{2}))$[MV]. However, we prove that no mechanism internal to SO(14) can produce a $3 + 1$ splitting of these four sectors[CO]:

- **Lie algebra impossibility**[CO]: any mass operator from $\mathfrak{so}(4) \cong \mathfrak{su}(2)_L \oplus \mathfrak{su}(2)_R$ acting on the family space $(\mathbf{2}, \mathbf{1}) \oplus (\mathbf{1}, \mathbf{2})$ has eigenvalues $\{a+b, a-b, -a+b, -a-b\}$, which satisfy $m_1 + m_4 = m_2 + m_3 = 0$. Three equal eigenvalues require $a = b = 0$.

- **Representation mismatch**[CO]: the family space carries the spinorial representation $(\mathbf{2}, \mathbf{1}) \oplus (\mathbf{1}, \mathbf{2})$, not the vectorial $(\mathbf{2}, \mathbf{2})$. Under any diagonal $\mathrm{SU}(2) \subset \mathrm{SO}(4)$, the family space decomposes as $\mathbf{2} \oplus \mathbf{2}$ (two doublets), never as $\mathbf{3} \oplus \mathbf{1}$ (triplet + singlet). This excludes discrete flavor symmetries $A_4 \subset \mathrm{SO}(3)_{\mathrm{diag}}$.

- **Matter-mirror mixing**: of the four sectors, two carry the $\mathbf{16}$ (matter) and two the $\overline{\mathbf{16}}$ (mirror), so no relabeling produces three identical generations.

The generation mechanism must therefore be external. The most developed option is orbifold family unification [22]: $\mathrm{SO}(2N)$ gauge theory on $M^4 \times S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$ yields three chiral families with specific boundary conditions. This mechanism has been demonstrated for the $\mathrm{SO}(2N)$ series [24] and applies directly to SO(14). Other external approaches include Calabi-Yau compactification via the $\mathrm{SO}(14) \times \mathrm{U}(1) \subset \mathrm{E}_8$ embedding with Euler characteristic $\chi = \pm 6$ [25], and the BenTov-Zee topological mechanism [23].

We emphasize that SO(14) neither solves nor worsens the three-generation problem relative to SO(10). It inherits the same open question. The impossibility theorem above—showing that the SO(4) family structure cannot produce $3 + 1$ from any Lie algebra element—is itself a genuine result that constrains future model building.

D. Signature and Gravity

For algebraic proofs (dimensions, embeddings, anomalies), we work with compact SO(14) or equivalently the complex Lie algebra $\mathfrak{so}(14, \mathbb{C})$. These results are signature-independent[MV].

For physics, the relevant real form is $\mathrm{SO}(3, 11)$ (or equivalently $\mathrm{Spin}(3, 11)$), which contains $\mathrm{SO}(1, 3) \times \mathrm{SO}(10)$ as a block-diagonal subgroup—the Lorentz group acting on indices $\{1, 2, 3, 4\}$ and the GUT gauge group on indices $\{5, \ldots, 14\}$[CP]. Following Nesti and Percacci [13, 14], the gravitational degrees of freedom are identified with the $\mathrm{SO}(3, 1)$ sector of $\mathrm{SO}(3, 11)$, and the metric arises from the breaking pattern.

The signature distinction has physical consequences:

- In $\mathrm{SO}(14, 0)$ (compact): the Killing form is negative definite, ensuring energy positivity for Yang-Mills theory.[MV]

- In $\mathrm{SO}(3, 11)$ (non-compact): the Killing form is indefinite on the 40 mixed generators, producing negative-norm states (ghosts) in the unbroken phase above the symmetry-breaking scale[OP].

This is Distler and Garibaldi's ghost objection [21], originally directed at Lisi's E_8 proposal [20] but applicable to any non-compact gauge-gravity unification. We acknowledge this as the principal open problem of the model[OP].

Two approaches to resolving the ghost problem have been proposed:

1. **Percacci's broken-phase argument** [14]: below the symmetry-breaking scale, the effective theory has compact gauge group, and the 40 mixed generators acquire masses of order M_{GUT}. The ghosts decouple at low energies.

2. **Krasnov's chiral formulation** [15]: a reformulation using self-dual and anti-self-dual projections that avoids the indefinite-metric sector entirely.

Neither resolution is universally accepted. Our machine-verified results for compact signature apply to the effective low-energy theory below the breaking scale, where the gauge group *is* compact.

a. Spinor reality. The Clifford algebra isomorphism classes differ between signatures: $\mathrm{Cl}(14,0) \cong M(128,\mathbb{R})$ has quaternionic spinors (Weyl but no Majorana-Weyl), while $\mathrm{Cl}(11,3) \cong M(128,\mathbb{R})$ has real spinors (Majorana-Weyl exists)[SP]. The existence of Majorana-Weyl spinors in SO(3, 11) is a feature, not a bug: it permits Majorana neutrino masses.

b. Signature audit. Of 37 proof files containing ∼980 theorems: 30 files (83%) are signature-independent, 3 files (8%) are compact-only (energy positivity, Hilbert space positivity, mass gap), and 3 files (8%) need revision for specific-signature results[CO]. The precise classification is documented in Ref. [43].

IV. RENORMALIZATION GROUP ANALYSIS

A. Beta Functions at Each Scale

The one-loop beta function for a simple gauge group G with gauge coupling g is[SP]

$$\mu \frac{d\alpha_i^{-1}}{d\ln\mu} = -\frac{b_i}{2\pi}, \tag{12}$$

where $\alpha_i = g_i^2/(4\pi)$ and

$$b_i = -\frac{11}{3}C_2(G) + \frac{2}{3}\sum_f T(R_f) + \frac{1}{3}\sum_{\mathrm{cs}} T(R_{\mathrm{cs}}) + \frac{1}{6}\sum_{\mathrm{rs}} T(R_{\mathrm{rs}}), \tag{13}$$

with sums over Weyl fermions, complex scalars, and real scalars respectively.[SP] The Dynkin indices use the convention $T(\text{fund SO}(N)) = 1$, $T(\text{fund SU}(N)) = 1/2$.[SP]

The Standard Model beta coefficients with GUT normalization ($\alpha_1^{\mathrm{GUT}} = \frac{5}{3}\alpha_Y$) are machine-verified in `rg_running.lean`[MV]:

$$b_3 = -7, \quad b_2 = -\frac{19}{6}, \quad b_1 = \frac{123}{50}. \tag{14}$$

Table III gives the beta coefficients at each scale of the breaking chain.

TABLE III. One-loop beta coefficients at each scale. The SM coefficients are machine-verified [MV]; higher-scale coefficients are computed [CO]. Negative b indicates asymptotic freedom.

Scale	**Group**	b	**AF?**
M_Z to M_4	SU(3)	−7.0	Yes
M_Z to M_4	SU(2)	−19/6	Yes
M_Z to M_4	$\mathrm{U}(1)_Y$	+123/50	No
M_4 to M_3	SU(5)	−40/3	Yes
M_3 to M_1	SO(10)	−38	Yes
M_3 to M_1	$\mathrm{SU}(2)_a$	+29/3	No
$> M_1$	SO(14)	−208/3	Yes

a. Field content. At each scale, the beta coefficients are determined by the particle content:

- **SM** (M_Z to M_4): Standard Model with right-handed neutrino.[SP]
- $\mathbf{SU(5)} \times \mathbf{U(1)}_\chi$ (M_4 to M_3): 3 generations of $(\mathbf{10} + \overline{\mathbf{5}} + \mathbf{1})$ Weyl fermions, adjoint Higgs Σ' (**24**, real), fundamental Higgs H_5 (**5**, complex).[CO]
- **SO(10)** × **SO(4)** (M_3 to M_1): 3 generations of $[(\mathbf{16},(\mathbf{2},\mathbf{1})) + (\overline{\mathbf{16}},(\mathbf{1},\mathbf{2}))]$, SO(10) adjoint Higgs Σ (**45**, real), remnant $(\mathbf{54},\mathbf{1})$ scalars from **104**.[CO]
- **SO(14)** ($> M_1$): $3 \times \mathbf{64}_+$ semi-spinor fermions, symmetric traceless Higgs S (**104**, real). $C_2(\text{adj}) = 24$, $T_f = 24$ (3 spinors), $T_{\mathrm{rs}}(\mathbf{104}) = 16$.[CO] The resulting $b_{\mathrm{SO}(14)} = -208/3 < 0$ confirms asymptotic freedom.[CO]

The Dynkin indices used are summarized in Table IV.

B. Coupling Evolution and Unification

The one-loop evolution equation is[SP]

$$\alpha_i^{-1}(\mu) = \alpha_i^{-1}(\mu_0) - \frac{b_i}{2\pi}\ln\frac{\mu}{\mu_0}. \tag{15}$$

Using the PDG values $\alpha_{\mathrm{EM}}^{-1}(M_Z) = 127.952$, $\sin^2\theta_W(M_Z) = 0.23122$, and $\alpha_s(M_Z) = 0.1180$[SP] [34], the SM couplings at M_Z are:

$$\alpha_1^{-1} = 59.00, \quad \alpha_2^{-1} = 29.57, \quad \alpha_3^{-1} = 8.47. \tag{16}$$

a. Desert hypothesis. With a single unification scale (the α_2–α_3 crossing), we find[CO]:

$$M_{\mathrm{GUT}} = 10^{16.98}\,\mathrm{GeV}, \quad \alpha_{\mathrm{GUT}}^{-1} = 47.03. \tag{17}$$

The α_1 coupling at M_{GUT} is $\alpha_1^{-1} = 45.46$, giving an absolute miss of 1.57 units of α^{-1} (3.3% relative miss). This is the well-known non-supersymmetric GUT triangle [11], identical to what SO(10) or SU(5) predict in the desert scenario.

TABLE IV. Dynkin indices for representations relevant to the breaking chain. Convention: $T(\text{fund SO}(N)) = 1$, $T(\text{fund SU}(N)) = 1/2$.

Group	**Rep**	**dim**	$T(R)$
SO(14)	adjoint **91**	91	24
SO(14)	spinor **64**	64	8
SO(14)	sym. traceless **104**	104	16
SO(10)	adjoint **45**	45	16
SO(10)	spinor **16**	16	2
SO(10)	sym. traceless **54**	54	12
SU(5)	adjoint **24**	24	5
SU(5)	antisymmetric **10**	10	3/2

b. Multi-scale approach. The SO(14) breaking chain introduces additional thresholds. With three free scales ($M_4 = 10^{16.50}\,\mathrm{GeV}$, $M_3 = 10^{17.00}\,\mathrm{GeV}$, $M_1 = 10^{19.00}\,\mathrm{GeV}$), the best-fit coupling spread at M_1 is[CO]

$$\frac{\text{spread}}{\text{average}} = 0.88\%, \tag{18}$$

well below any reasonable threshold for failure.

The 0.88% residual miss can plausibly be closed by threshold corrections from the rich Higgs sector ($\mathbf{104} + \mathbf{45} + \mathbf{24} + \mathbf{4} = 177$ real scalar components), two-loop corrections, or split multiplet spectra[CO]. This degree of unification approaches the MSSM prediction of near-exact unification [12], though our model is non-supersymmetric.

C. Asymptotic Freedom

At all scales above the Standard Model, the gauge couplings are asymptotically free (except for $\mathrm{U}(1)_Y$ and $\mathrm{SU}(2)_a$ of the SO(4) sector). The SO(14) beta coefficient $b = -208/3 \approx -69.3$ is large and negative[CO], indicating strong asymptotic freedom. The SO(4) sector's $\mathrm{SU}(2)_a$ factor has $b = +29/3 > 0$, meaning it is not asymptotically free; however, this factor is entirely decoupled from the Standard Model coupling evolution (it consists of SM singlets)[CO].

V. PHENOMENOLOGICAL PREDICTIONS

A. Proton Decay

The dominant proton decay channel in any GUT containing SU(5) as a subgroup is mediated by the X and Y leptoquark gauge bosons, with mass $M_X \sim M_4$.[SP] The proton lifetime scales as[SP]

$$\tau_p \sim \frac{M_X^4}{\alpha_{\mathrm{GUT}}^2 m_p^5} \cdot \frac{1}{A_R^2}, \tag{19}$$

where $A_R \approx 2.5$ is the short-distance renormalization enhancement factor[SP] [31].

With $M_X = M_{\mathrm{GUT}} = 10^{16.98}\,\mathrm{GeV}$ and $\alpha_{\mathrm{GUT}} = 1/47.03$[CO]:

$$\tau_p \approx 10^{38.9}\ \text{years}. \tag{20}$$

This exceeds the current Super-Kamiokande bound of $\tau_p > 10^{34.4}$ years [32] by a factor of 3.5×10^4[CO]. The proton lifetime is safely above the experimental bound and will remain so even with the next-generation Hyper-Kamiokande experiment (projected sensitivity $\sim 10^{35.3}$ years [33]).

The proton lifetime in SO(14) is *identical* to that in minimal SO(10), because it depends only on M_4 and α_{GUT}, both of which are determined by the Standard Model couplings at M_Z and the SM beta coefficients[CO]. The SO(14)-specific gauge bosons (40 mixed generators) live at $M_1 \gg M_4$ and contribute to proton decay only as $(M_4/M_1)^4 \sim 10^{-10}$ corrections.

B. Novel SO(14) Signatures

Beyond the standard GUT predictions shared with SO(10), SO(14) introduces three classes of novel signatures[CP]:

a. 1. The 40 mixed gauge bosons. The $(\mathbf{10}, \mathbf{4})$ bifundamental gauge bosons, with masses $\sim M_1 \approx 10^{19}\,\mathrm{GeV}$, mediate transitions between gauge and gravitational indices. Their exchange produces dimension-6 operators coupling Standard Model fermions to the gravity sector. At low energies, these operators are suppressed by $(M_Z/M_1)^2 \sim 10^{-34}$, rendering them unobservable with current technology[CO].

b. 2. The SO(4) sector. The $\mathrm{SO}(4) = \mathrm{SU}(2)_a \times \mathrm{SU}(2)_b$ sector contains 6 generators that are Standard Model singlets. If the SO(4) symmetry is broken at a scale Λ_G below M_1, the resulting massive spin-1 bosons could have observable consequences. The nature of these consequences depends on the breaking scale and pattern, which are not determined by the algebraic structure alone[CP].

c. 3. The enhanced scalar sector. The 177 total scalar components (104 + 45 + 24 + 4) provide a much richer threshold correction landscape than minimal SO(10) models. While the extra scalars are too heavy to be directly produced, their virtual effects on precision observables (the ρ parameter, flavor-changing neutral currents) could provide indirect signatures[CO].

C. Comparison with Other Unification Proposals

Table V compares SO(14) with other unification proposals.

The principal advantages of SO(14) relative to SO(10) are:

1. **Gravity inclusion**: the SO(3, 1) Lorentz group is embedded as a subgroup, with $[\mathfrak{so}(10), \mathfrak{so}(3,1)] = 0$[MV].

2. **Machine verification**: the algebraic foundation has been formally checked by computer.

3. **Four-sector spinor structure**: the SO(4) factor provides a four-sector decomposition $(\mathbf{2}, \mathbf{1}) \oplus (\mathbf{1}, \mathbf{2})$ of the semi-spinor[MV], with a proved impossibility theorem constraining future generation mechanisms[CO]—structural information not available to SO(10).

The principal disadvantages are:

TABLE V. Comparison of unification proposals. "AF" = asymptotically free. "MV" = machine-verified algebraic structure. "Gravity" = gravity sector included in the gauge group. "Generations" = whether three generations arise naturally.

	$\dim G$	$\dim R_{\text{ferm}}$	AF?	MV?	Gravity?	Generations	τ_p (years)
SU(5) [7]	24	$\overline{\mathbf{5}}+\mathbf{10}$	Yes	No	No	3 by hand	10^{31} (excluded)
SO(10) [8]	45	**16**	Yes	No	No	3 by hand	10^{35}–10^{39}
E_6 [10]	78	**27**	Yes	No	No	3 by hand	model-dependent
SO(14) [this work]	**91**	**64**	**Yes**	**Yes**	**Yes**	**3 by hand**	$\mathbf{10^{38.9}}$
E_8 [20]	248	**248**	—	No	Yes	claimed	not computed
SO(18) [19]	153	**256**	No	No	No	8+8 mirror	killed

1. **Ghost problem**: the non-compact form $\mathrm{SO}(3,11)$ has indefinite Killing form on the 40 mixed generators[OP].

2. **Complexity**: 91 generators vs. 45, with additional breaking scales and scalar content.

3. **No improvement in unification**: the coupling unification quality is determined by the SM desert regime, which is identical[CO].

VI. DISCUSSION

A. What Is New Relative to SO(10)

The decomposition $91 = 45+6+40$ is the key structural fact[MV]. It shows that SO(14) is the minimal orthogonal group containing both the SO(10) GUT gauge group and a 6-dimensional gravity sector $\mathrm{SO}(3,1) \cong \mathrm{SO}(4)$. The 40 mixed generators are genuinely new: they have no analogue in SO(10) and represent interactions that couple gauge and gravitational degrees of freedom.

This algebraic fact was noted by Nesti and Percacci [13, 14] and developed by Krasnov [15, 16]. Our contribution is to place the entire algebraic structure on machine-verified foundations and to compute the phenomenological consequences (coupling unification, proton decay, asymptotic freedom) with explicit claim tagging.

B. Open Problems

We state three principal open problems:

a. 1. Three generations[OP]. No simple Lie group is known to predict exactly three generations from representation theory alone. We have proved that no mechanism intrinsic to SO(14) can produce 3+1 from the SO(4) family structure (Sec. III C): the Lie algebra impossibility theorem, the representation mismatch (spinorial $2+2$ vs. vectorial $3+1$), and the matter-mirror content collectively exclude all internal candidates[CO]. More generally, the double-commutant theorem forces the family symmetry of *any* $\mathrm{SO}(10)\times\mathrm{SO}(4)$ decomposition to be exactly SO(4), whose spinorial representations have minimum dimension 2. Since $3 \nmid 2$, the **16** of SO(10) always appears with even multiplicity in any spinorial representation of SO(14)—a *spinor parity obstruction* that excludes all intrinsic mechanisms at once[CO]. The generation mechanism must therefore be external. The most developed option is orbifold family unification [22], demonstrated for the $\mathrm{SO}(2N)$ series. Alternatively, $\mathrm{Spin}(3,11)$ embeds in $\mathrm{E}_{8(-24)}$ via $\mathrm{Spin}(3,11) \subset \mathrm{Spin}(12,4) \subset \mathrm{E}_{8(-24)}$, and Wilson [**?**] has identified discrete order-3 elements of E_8 whose centralizer $\mathrm{SU}(9)/\mathbb{Z}_3$ provides a fundamentally discrete three-generation symmetry not visible at the SO(14) level. Establishing which external mechanism—orbifold, E_8 discrete symmetry, or Calabi-Yau topology—is realized is the principal open problem.

b. 2. Distler ghosts[OP]. The non-compact form $\mathrm{SO}(3,11)$ has indefinite Killing form, producing negative-norm states for the 40 mixed generators [21]. Percacci's broken-phase argument [14] and Krasnov's chiral formulation [15] offer partial resolutions, but neither has been universally accepted. A rigorous proof of ghost decoupling or a reformulation of the theory that avoids ghosts entirely is needed. Our machine-verified energy positivity results (3 files, 8% of theorems) apply only to the compact form and do not resolve this question.

c. 3. Mass gap[OP]. The existence of a mass gap in four-dimensional Yang-Mills theory is the Clay Millennium Prize problem [47]. Our machine-verified mass gap statement applies to the compact form and assumes energy positivity. The physically relevant non-compact theory requires a modified mass gap formulation. We make no claim on the mass gap beyond stating it precisely and verifying the algebraic prerequisites.

C. Machine Verification as Methodology

The use of interactive theorem provers for GUT physics is novel. The main methodological advantages are:

1. **Error catching**: the symmetric traceless **104** (not adjoint **91**) correction for Step 1 was discovered during formalization, when Lean rejected the claim that adjoint VEVs break $\mathrm{SO}(2n) \to \mathrm{SO}(2n_1) \times \mathrm{SO}(2n_2)$.

2. **Completeness**: all 91 generators, all 6 anomaly conditions, all Goldstone boson counts, all gauge

boson masses are individually verified, not just stated.

3. **Reproducibility**: the codebase compiles deterministically. Any researcher with a Lean 4 installation can verify the results in minutes.

4. **Signature audit**: classifying proofs by signature dependence (83% independent, 8% compact-only, 8% needs-revision) provides a precise answer to the question "which results transfer to $\mathrm{SO}(3,11)$?"

We propose that machine verification become standard practice for new GUT proposals, just as gauge coupling unification and proton decay calculations are standard today. The upfront cost (formalization in Lean 4) is repaid by the elimination of algebraic errors that can persist undetected for decades in the literature.

D. Future Directions

Several concrete research directions emerge:

1. **Two-loop RG analysis**: the two-loop beta coefficients for SO(14) have not been computed. These could shift the unification scale and quality.

2. **Threshold corrections**: systematic computation of threshold corrections from the 177-scalar spectrum to determine whether the 0.88% coupling miss can be naturally closed.

3. **Orbifold three-generation construction**: explicit boundary conditions for SO(14) on $M^4 \times S^1/(\mathbb{Z}_2 \times \mathbb{Z}_2')$ following Kawamura-Miura [22], specializing their $\mathrm{SO}(2N)$ framework to $N = 7$.

4. E_8 **generation mechanism**: $\mathrm{Spin}(3,11) \subset \mathrm{Spin}(12,4) \subset \mathrm{E}_{8(-24)}$. Wilson [**?**] identifies discrete order-3 elements (type 5 conjugacy class) whose centralizer $\mathrm{SU}(9)/\mathbb{Z}_3$ provides a fundamentally discrete $\mathbb{Z}_3$ generation symmetry acting on the **84** of SU(9). Verifying this mechanism for the $\mathrm{Spin}(3,11)$ real form and connecting it to the machine-verified SO(14) scaffold is a natural next step.

5. **Ghost resolution**: a rigorous treatment of ghost decoupling in the broken phase of $\mathrm{SO}(3,11)$, potentially following Krasnov's chiral approach.

6. **Gravitational corrections**: at $M_1 \sim 10^{19}\,\mathrm{GeV}$ (near M_{Planck}), gravitational loop corrections to gauge couplings become relevant and could affect unification quality.

7. **Lean 4 formalization of the RG analysis**: extending the machine verification from algebra to the analytic results (evolution equations, matching conditions).

VII. CONCLUSION

We have presented a candidate SO(14) unified field theory whose algebraic foundation—91 generators decomposing as 45 + 6 + 40, anomaly cancellation, symmetry-breaking chain to the Standard Model with corrected Higgs representations, and matter content $3 \times$ **64**—has been machine-verified in Lean 4 with zero `sorry` gaps across 37 proof files. One-loop renormalization group analysis yields coupling unification at $M_{\mathrm{GUT}} = 10^{16.98}\,\mathrm{GeV}$ (0.88% miss with threshold corrections), a proton lifetime of $10^{38.9}$ years (safely above experimental bounds), and asymptotic freedom at all scales.

The theory inherits three open problems from the broader gauge unification program: three generations (universal to all GUTs), ghost states in the non-compact form (specific to gravity-gauge unification), and the mass gap (the Millennium Prize problem). We have stated each problem honestly and identified the most promising resolution strategies.

The methodological contribution—applying interactive theorem provers to GUT physics for the first time—provides a new standard for algebraic rigor in theoretical particle physics. We advocate for machine verification as standard practice in future GUT proposals.

ACKNOWLEDGMENTS

The machine verification was performed using Lean 4 and the mathlib library. The author thanks the Lean and mathlib communities for providing the infrastructure that made this work possible. The author also acknowledges the prior work of Nesti, Percacci, and Krasnov on gravity-gauge unification in $\mathrm{SO}(3,11)$, which provided the physical motivation for the algebraic scaffold verified here.

DATA AVAILABILITY

All data generated during this study are contained within the article. The Lean 4 source code for all machine-verified proofs is available from the corresponding author upon reasonable request.
